14

Entrepreneurship, Stages of Development, and Industrialization

Zoltan J. Acs and Wim Naudé

14.1 Introduction

Entrepreneurs play an important part in economic growth and development. This has been a key insight since the contribution of Schumpeter (1911) and others (for a discussion, see Naudé 2011a). Entrepreneurs are also vital in the process of structural change or industrialization (Gries and Naudé 2010), a process without which development is not possible, as many of the contributions in Part I of this book have explained. As formalized in Gries and Naudé’s (2010) model of entrepreneurship and structural change, entrepreneurial innovation leads to the reallocation of resources from the traditional (agricultural) sector to the modern (manufacturing) sector. There is substantial agreement that recovery after the 2008–09 global financial and economic crises and the challenge of climate change will require more, not less, of such entrepreneurial innovation. What is needed are quality jobs through low-carbon industrialization (Mayer 2010; Naudé 2010b). As was made clear in Chapter 1 there is now a growing rediscovery of industrial policy as being necessary to overcome a number of market failures that inhibit entrepreneurial innovation in job creation and low-carbon industrialization. This implies an industrial policy where the relationship between government and entrepreneurs (the private sector) is important. Unlike in the past where industrial policy was either focused on creation and growth of state-owned firms or alternatively consisted merely of broadly functional policies without consideration for firm or entrepreneurial specifics, the requirement now is that future

1 As put by The Economist (March 14, 2009: 3) ‘The lights may have gone out on Wall Street, but Silicon Valley continues to burn bright’.
Entrepreneurship and Stages of Development

industrial policy ought to be a nuanced partnership between entrepreneurs and the state.

In this chapter we outline some considerations for such an industrial policy where the entrepreneur–state nexus is paramount. Moreover, we argue that such an industrial policy will need to take into consideration that the entrepreneur–state nexus is evolving, and that it depends on the stage of development of a particular country. This builds on the recent contributions of Acs (2010) and Acs and Szerb (2009), in which the different roles of entrepreneurship across a country’s stages of development is recognized.

In the next section we discuss the role of entrepreneurs in industrialization. Then in Section 14.3 we analyse the role of entrepreneurship across various stages of development, with particular consideration of the empirical evidence and on using the Global Entrepreneurship Development Index (GEDI) as a guide to inform industrial policy aimed at entrepreneurial innovation. This section relies heavily on Acs and Szerb (2009) and Acs (2010). In Section 144 we bring together these two strands of thinking and tease out the implications for industrial policy across various stages of development. Section 14.5 concludes.

14.2 Entrepreneurship and industrialization

Gries and Naudé (2010) provide a model to illustrate the role of the entrepreneurial innovation in industrialization. Here entrepreneurs fulfil essential roles. First, they create new firms outside the household, offering new products and introducing new processes that provide information as a ‘lead’ activity. Second, they increase the size of firms (and wage employment) by making use of scale economies. Such larger firms tend to specialize, and the clustering of specialized firms can give rise to localization economies, further encouraging innovation and specialization. Third, entrepreneurs can raise the returns to human and physical capital and so provide incentives for further investment and education.

Entrepreneurs may not automatically provide these functions, as they will be constrained by market failures. Industrial policy may thus be justified. Rodrik (2007), recognizing this, discusses a number of such entrepreneurship-inhibiting market failures. This can occur in financial, labour, product, and knowledge markets. He remarked that in developing countries ‘the deck is stacked against entrepreneurs who contemplate diversifying into non-traditional areas’ (ibid.: 7).

Consider first the creation of new firms and the market failures due to the information it generates. Early or lead entrants into a market or production process reduce the uncertainty for followers by providing information as to its
Entrepreneurship and Stages of Development

profitability (Hoff 1997). It has been described as a ‘cost-discovery’ function by Hausmann and Rodrik (2003). An industrial policy that facilitates this cost-discovery function of entrepreneurs needs to be flexible and moreover to encourage experimentation. According to Aghion (2009: 15) entrepreneurially consistent industrial policy needs to be able to facilitate experimental state intervention, but must be able to ‘stop the intervention if it turns out not to be efficient’. There is wide opposition to industrial policies that, by eschewing an approach consistent with entrepreneurship, have few mechanisms to get rid of inefficient firms. Just as firm entry is important, assuming new opportunities, providing higher returns to human capital, and signalling what an economy may be good at producing, so firm exit, once a firm has failed, is important too. According to Campbell (2009: 1), citing the case of Pakistan, industrial policy can fail when governments lack the strength ‘to cut support to unsuccessful companies and industries’ that are politically well-connected.

Second, market failures often prevent firms from growing. An empirical regularity associated with the failure of industrialization in much of Africa is the failure of small firms to grow—Page in this volume argues that these firms need to ‘learn to compete’. In contrast, the growth in firm size as a country industrializes is a ‘stylized fact’ of economic development. It depends, however, crucially on entrepreneurship and specifically entrepreneurial talent or ability, as illustrated by Murphy, Shleifer, and Vishny (1991). Market failures result in the misallocation of entrepreneurial talent.

The role of entrepreneurial ability in the industrial success of the newly industrialized economies (NIEs) has been emphasized by Nelson and Pack (1999). They offer a dual-economy model to explain the structural transformation of economies, such as Korea and Taiwan, from being characterized by a ‘craft’ sector to a ‘modern’ economy. They assign a key role to the ‘effectiveness of entrepreneurship’ (or entrepreneurial ability), which they see as a vital determinant of the rate of assimilation of technology (ibid. 1999: 420). They stress the imitative role of entrepreneurship as well as its role in taking on uncertainty, given that the adoption of (mostly) foreign technology by entrepreneurs in these countries entails significant risk-taking (ibid. 1999: 418). By performing this task, the entrepreneur is the essential mechanism causing new knowledge, as embodied for instance in foreign technology, to ‘spill over’ (Braunerhjelm, Acs, and Audretsch 2010).

2 The current European industrial policy (EC 2005, 2007) recognizes this role of lead entrants. For example it has adopted a ‘lead market initiative’ which consists of ‘legal and regulatory frameworks, fostering of open-innovation mechanisms, standards, public procurement practices, intellectual property protection, or the availability of venture capital’ with the aim to ‘lift obstacles that hinder the development of new markets’ (EC 2007: 7–8).
Entrepreneurship and Stages of Development

The third role of entrepreneurship inhibited by market failures is that of creating incentives for further investments in human-capital formation. Since the process of industrial catching up requires a higher level of skilled labour, entrepreneurs cause an increase in the demand for educated labour. This leads to an overall improvement in human capital in a country, in turn facilitating the imitation and adoption of foreign technology. Nelson and Pack’s model implies that a ‘rapid’ expansion of skilled labour can only be absorbed if entrepreneurial ability is high, and that without entrepreneurial ability the returns to physical and human capital are low (Nelson and Pack 1999: 423). Entrepreneurial ability therefore has positive externalities that could justify support for it within industrial policies.

14.3 Entrepreneurship across the stages of development

In his classic text, Rostow (1960) suggested that countries go through five stages of economic growth:

(i) the traditional society
(ii) the preconditions for take-off
(iii) the take-off
(iv) the drive to maturity
(v) the age of high mass consumption.

While these stages are a simplified way of looking at the development of modern economies, they identify critical events. When the Soviet Union did not develop into a mass consumption society (in part due to a lack of total factor productivity), the stages approach to economic growth went out of fashion.

However, influenced by recent developments in economics, Porter, Sachs, and McArthur (2002) have provided a modern rendition of this approach by identifying three stages of development as opposed to growth and two transitions. The three stages are:

(i) a factor-driven stage
(ii) an efficiency-driven stage
(iii) an innovation-driven stage.

While Rostow (1990) focused on the age of high mass consumption, Porter, Sachs, and McArthur (2002) following recent developments in the economics of innovation focuses on the innovation-driven stage. Historically, an elite

3 Keller (2004: 752) points out that for most countries, foreign sources of technology account for 90 per cent or more of local productivity growth.
entrepreneurial class appears to have played a leading role in economic development. Today we believe that they are also crucial for the innovation-driven stage. The transition to the innovation-driven stage is characterized by increased activity by individual agents. In the innovation-driven stage knowledge provides the key input. In this stage the focus shifts from firms to agents in possession of new knowledge. The agent decides to start a new firm based on expected net returns from a new product. The innovation-driven stage is biased towards high value-added industries in which entrepreneurial activity is important.

Institutions dominate the first two stages of development. In fact, innovation accounts for only about 5 per cent of economic activity in factor-driven economies and rises to 10 per cent in the efficiency-driven stage. However, in the innovation-driven stage, when opportunities have been exhausted in factors and efficiency, innovation accounts for 30 per cent of economic activity. We see an S-shaped relationship between entrepreneurship and economic development because in the first transition stage entrepreneurship plays a minimal role in productive transformation. It increases in the efficiency-driven stage. However, as we move from the efficiency-driven stage to the innovation-driven stage (the knowledge-driven stage) entrepreneurship plays a more important role, at an increasing rate but then leveling off as economies become fully developed.

Figure 14.1 shows the relationship between entrepreneurship and economic development. Entrepreneurship is considered to be an important mechanism

Figure 14.1. Entrepreneurship and the corresponding stages of development
Source: Acs and Szerb (2009).
Entrepreneurship and Stages of Development

for economic development through employment, innovation, and welfare. The intersection of the S-curve on the vertical axis is consistent with Baumol’s (1990) observation that entrepreneurship is also a resource, and that all societies have some amount of economic activity, but that activity is distributed between productive, unproductive, and destructive entrepreneurship.

What is crucial is to determine how much productive entrepreneurship we have in countries at different stages of development? The S-curve suggests that in the factor-driven stage a relatively small amount of entrepreneurial activity is productive; that is, it creates economic and/or social value. As mentioned earlier, this increases sharply through the efficiency-driven stage and levels off in the innovation-driven stage of development. As institutions are strengthened, more and more entrepreneurial activity is shifted towards productive entrepreneurship strengthening economic development. We will discuss the implications of this for industrial policy in the next section.

A related question is ‘What are the other entrepreneurs doing?’ The answer is that if the supply of entrepreneurship is constant, then the majority of entrepreneurs are engaged in either destructive entrepreneurship (destroying social value) or unproductive entrepreneurship (not increasing social value). For example entrepreneurship may thrive on and encourage the existence of a black market, the best and the most talented may be engaged in bureaucratic rent-seeking or risky and (at times) illegal ventures that destroy social value even when adding to the wealth of the individual in concern. If a constant proportion $X$ of the population is engaged in entrepreneurship and only a small fraction of this is in productive entrepreneurship, the rest are destroying value. Building better institutions and changing the incentive structure of the society can only eliminate this valley of backwardness above the S-curve. All of this requires good government and governance, and industrial policy focusing on the broader institutional environment may play a crucial role in this case.

To identify the level of entrepreneurial activity in a country corresponding to the stage of development and its role in industrial policy we need good measures for entrepreneurship. The existing measures do not fully capture the essence of entrepreneurship, empirically or conceptually. GEDI is an independent index that provides a comprehensive measure of entrepreneurship. The index draws on previous measures of economic freedom, competitiveness, and entrepreneurial activity but improves on each of these by providing a more focused and quality-oriented approach.

As illustrated in Table 14.1 three sub-indexes of activity, aspiration, and attitudes combine to constitute the entrepreneurship super-index. While other indices have focused on entrepreneurship at the innovation-drive stage, the newly created GEDI takes into account entrepreneurship at all stages of development. First, the three entrepreneurial sub-indices are not of equal importance. The attitude sub-index measures society’s basic attitudes toward

Entrepreneurship and Stages of Development

entrepreneurship through education and social stability. The activity sub-index measures what individuals are actually doing to improve the quality of human resources and technological efficiency. The aspiration sub-index measures how much of the entrepreneurial activity is being directed toward innovation, high-impact entrepreneurship, and globalization. The sub-indexes are based on their constituent pillar scores. The pillars, in turn, are based on the interaction between their constituent individual and institutional variables. The incorporation of institutional variables is a unique feature of the GEDI and reflects the qualitative aspect of entrepreneurship. Understanding the sub-indexes and their changing importance towards entrepreneurial development across stages of development provides a useful approach towards informing a more appropriate set of industrial policies.

14.4 Entrepreneurship and industrial policy across stages of development

Despite the threefold important role played by individual entrepreneurs as was discussed in Section 14.2, and despite the clear evidence that the role of the entrepreneur differs across stages of development, many earlier industrial policies largely failed to explicitly incorporate the entrepreneur and to pay attention to the developmental stage of a country. This is especially the case in Africa where industrial policy is now seen to be largely unsuccessful (see Chapter 9 in this volume)—with the possible exception of South Africa. In Africa market and government failures resulted in a much larger misallocation of entrepreneurial ability towards unproductive and even destructive activities (as mentioned earlier; see also e.g. Baumol 1990; Baumol, Litan, and Schramm 2007) and in an inappropriate emphasis on stimulating economic activity and growth in a manner that was not optimal for entrepreneurship given these countries’ levels of development.

In contrast, there is considerable evidence that in the countries where industrial policies have been more successful—such as the NIEs and China—that industrial policy more properly considered the nature of a country’s entrepreneurs and their relation to the state. Thus for instance in Singapore and Korea, where the entrepreneurial base was judged to be lacking, industrial policy was at first aimed at complementing and strengthening the domestic entrepreneurial base, through allowing in much more foreign entrepreneurship and by

---

4 Central in the country’s industrial policy was the state-owned creation of the largest venture capital fund for manufacturing on the African continent, the Industrial Development Corporation (IDC) of South Africa in 1940. In the following sections we will stress the potential importance of an entrepreneurial approach to industrial policy of promoting venture capital in developing countries.
providing financial support to allow entrepreneurs to take on more risk in imitating and adopting foreign technology (Nelson and Pack 1999). And in Taiwan and Japan, where the entrepreneurial base was fairly strong to begin with, more limitations were placed on foreign entrepreneurs.

China’s economic transformation since the late 1970s also shows a measure of consideration of entrepreneurship. Thus, for instance, Siebert (2007: 899) remarks that ‘the Chinese now show a larger acceptance of the market economy than the three large continental countries of Europe’. He describes how the Chinese reforms fostered the emergence of more productive enterprises, not by dismantling or privatizing state-owned enterprises upfront (as in Eastern Europe or some African countries), but of maintaining these and ‘simply by letting new economic activities develop outside the government controlled sector’ (ibid.: 900). China also allowed the growing class of private sector entrepreneurs to influence the evolution of the institutional framework shaping its industrial policy—a process described as ‘institutional entrepreneurship’.

Reasons for the neglect of the entrepreneur in industrial policy in the past may be due to the likelihood that the nature of the firm was not always adequately understood (Lazonick 2009), in other words that early development economics did not see entrepreneurship as a binding constraint on economic development (Naudé 2011b). We can also add to this the argument of this chapter, namely that the measurement of entrepreneurship was a neglected area, and that the nature of the contribution of entrepreneurship across various stages of development was not properly recognized.

Understanding the nature of the firm as described should be seen in conjunction with the advances in recent years of distinguishing the role of entrepreneurship across various stages of development. This recognizes that different types of industry develop or evolve over the course of a country’s development path (Lin and Chang 2009) and that different types of industry and firm heterogeneity entail different types of entrepreneurship, which in turn requires different types of support from the government. Hart (2001), for instance, makes a distinction between a ‘developmental state’ and a ‘regulatory state’, arguing that a developmental state, which is more hands-on and leading in the process of industrialization, is more suited when a country’s industry will benefit from centralization and intervention—i.e. where the firm and the entrepreneur is still operating well within the technological frontier. A similar argument is made by Phan, Venkataraman, and Velamuri (2008) in a study of entrepreneurship in emerging countries. They conclude:

…studies of entrepreneurial regions across the world…have underscored the critical role of governments at different levels in the emergence of these regions… the magnitude of government influence, which is significant in the early stages of development, seems to decline in later stages relative to other factors…The
Entrepreneurship and Stages of Development

Explanations for this vary from the traditional factor substitution wherein government kick-starts the development of a sector, which then becomes attractive for private capital to accumulate, to the post-modern institutionalization, in which the development of such institutions as intellectual property regimes engender capital accumulation (ibid.: 325).

Thus they find that in early stages of development government intervention is needed to address market failures and to kick-start growth. They see this intervention as a prerequisite for the later development of an entrepreneurial economy.

The discussion so far suggests very strongly that there is no ‘one size fits all’ as far as industrial policy is concerned. This is in line with Chapter 5, where Hobday argues that instead of trying to ape the successful Asian industrializing countries, poor countries should adopt appropriate, home-grown industrial policies based on their resources, capabilities, and stage of development. Because innovation, as the fundamental driver of economic growth makes a different contribution across stages, industrial policy should be closely aligned (consistent) with innovation policy. Indeed it is recognized in the innovation literature that ‘innovation ambitions and policies have to be adapted to levels of development’ (Aubert 2004: 14).

The relationship between entrepreneurs and government and the implications for industrial policy and innovation (also informed by the GEDI) through various phases of development are summarized in Table 14.2.

In the table the left-hand column refers to three stages of development: the factor-driven stage, the efficiency-driven stage, and the innovation-driven stage—as described in the previous section. In the second column this is set against the dominant private sector mode, in the third column against the characteristics of the innovation system (given that industrial policy should primarily support innovative entrepreneurship) and on the final column against the type of state orientation most conducive for the development of the private sector mode.

The table indicates that at an early stage of development the entrepreneurial base is still small, and that private sector activity is mainly in dispersed, low-productivity traditional activities. In such a stage of development, states are very often fragile (see Naudé, McGillivray, and Santos-Paulino 2011) and the major development challenge is to move the state from being fragile to being facilitating. In other words, the state establishes legitimacy, authority, and capacity, and starts to put in place basic framework conditions for investment and productivity growth. This will enable a core of entrepreneurship to emerge, most often in accordance with the country’s comparative advantage, and will prepare the economy for the efficiency-driven path.

5 Indeed, Lin defines a ‘facilitating state’, as a ‘state that facilitates the private sector’s ability to exploit the country’s areas of comparative advantage’ (Lin and Chang 2009: 484).

*Source*: author’s compilation based on the discussions in Altenburg (2009); Acs and Szerb (2009); Aubert (2004), and Porter (2004).
To fully embark on this path of efficiency-driven growth, however, the state needs to expand its intervention in the economy to ‘defy’ the comparative advantage through selective industrial policies. This will, for instance, allow economies of scale to be reaped, which will encourage self-reinforcing agglomerations, facilitate growth in firms’ size, and will see a greater role, for instance, for state-owned enterprises (SOEs) and multinational enterprises (MNEs) as the latter makes use of special economic zones and other incentives.

During the efficiency-driven stage, innovation policies as subset of industrial policy increase in importance. Thus for instance as suggested in column 4, row 2, intellectual property protection is often not seen as being of such great importance in earlier stages of development, only becoming more important when a country has already entered a rather more advanced stage of development (Aubert 2004). Thus, as shown in the efficiency-driven stage of development, public R&D starts to play a more important role but it is less important in the factor-driven stage. Impact evaluations have found that public R&D can stimulate total investment in R&D and can thus crowd-in private R&D (Taymaz and Üçdoğru 2009).

In earlier phases of development, the adoption and eventual adaptation of technologies are important to encourage. Policies that can do this include those that improve skills, organizational learning, and attitudes and culture (Lindahl 2005).

Aubert (2004) focuses on the obstacles to entrepreneurial innovation in developing countries in earlier stages of development. He recommends measures and reforms to address broad or ‘functional’ obstacles, such as business environment constraints. This is indeed what typical private-sector development initiatives attempt to improve.

At some point, the country’s sectoral development will be such that it needs a flexible industrial policy, so as to shift again towards being less interventionist, more functional but also, perhaps surprisingly, more selective. Many countries embark on trade liberalization during this phase of their development. Examples given in this chapter include the EU, the USA, and India. China’s two-track approach since 1978 can be seen as a variant of this shift, whereby the change is gradually introduced by allowing a more liberalized private-sector economy to develop whilst not disbanding state-owned enterprises.

As is also shown in column 4 of Table 14.2, and based on the GEDI, entrepreneurially oriented industrial policies should at different stages focus differently on attitudes, activities, and aspirations. Attitudes are an essential prerequisite for either activity or aspirations. This is in part cultural, as certain societies (e.g. communism and feudalism) outlawed entrepreneurship. Attitude is followed by activity, and after activity, aspirations become important. In some sense, this process is cumulative over time, but it has large overlaps as
Entrepreneurship and Stages of Development

well. In a factor-driven (agricultural economy) the focus needs to be on entrepreneurial attitudes in the population. In an efficiency-driven (manufacturing) economy individual entrepreneurs need to be encouraged to start businesses. In an innovation-driven (knowledge-based) economy some people need to create very large and successful businesses. The role of institutional and individual variables used in the construction of the indices is also an important aspect of the development process. While institutional improvement is vital for factor-driven countries to advance to the next level of development, the enhancement of individual characteristics is increasingly critical for innovation-driven economies.

Thus important policy implications for the countries at different levels of development emerge from the GEDI rankings.

Factor-driven economies need to focus on entrepreneurial attitudes, start to develop activity, and begin the process of enabling entrepreneurial aspirations. Here an instructive example is from India, where entrepreneurship has been resurgent since the early 1990s. It has made strong contributions to growth through innovation—as has been demonstrated by the country’s vibrantly growing ICT sector. A number of policy initiatives have been important in facilitating this growth. Das (2009) identifies in this regard most importantly a change in culture and attitudes towards entrepreneurs.

The key focus of efficiency-driven economies should be on entrepreneurial activity. Here it is also important that entrepreneurs start to be more socially responsible—making increasing contributions to health, education, and welfare, so that ‘the business community sees development issues as their problem, too’ (Das 2009: 3), and that governments start to provide more supported entrepreneurship and innovation through creation of venture capital funds as they did for instance in India (Mani 2011).

However, continuous improvement of attitudes and the development of entrepreneurial aspirations are also important. In innovation-driven economies, the key focus should be on aspirations. However, both attitudes and activity need to be improved to maintain balance across the three sub-indices. This is also highlighted in Table 14.3.

These policy recommendations are reflected in column 4 of Table 14.2. It is important to note that there is a bidirectional causality between innovation, industrialization, and stages of development. At a high level of per capita GDP, governments spend more on R&D and universities, creating a supporting environment for creative pursuits, including technological innovation, which spurs further industrial sophistication.

The greater selectivity during the innovation stage (and to an extent already during the efficiency-driven growth stage) stems from the requirement of focusing on the small subset of firms that are really innovative. Not all firms are innovative. Innovative entrepreneurship is sometimes also seen as
synonymous with high-impact or high-growth entrepreneurship (HGE; Ler-
ner 2009; Shane 2009; Wong, Ho, and Autio 2005), and their firms are
described as ‘gazelles’ (Stam et al. 2009; Teruel and De Wit 2011). These HGE
firms are disproportionately important for economic growth and develop-
ment—as put by Shane (2009: 145) ‘a tiny sliver of companies accounts for the vast majority of the contribution to job creation and economic growth’.

Selectivity and targeting have the benefits of overcoming shortcomings of past efforts, raising the effectiveness and sustainability of industrial policies, and conserving resources (Stam et al. 2009).

Shane (2009) also cautions against targeting potentially HGE firms, but points out that these types of firms very often tend, at least in advanced economies, to be financed disproportionally by venture capital. He refers to data that show that in the USA in 2003 firms that were supported by venture capital employed almost 10 per cent of all the private sector. Of course the difficulty is that venture capital funding is still very underdeveloped in developing and emerging economies in the first stages of development, where innovative entrepreneurs rely more on internal funding and where many donor and other entrepreneurship programmes have aimed at expanding debt financing to firms. This implies that if in future the benefits of selectivity are to be gained, that perhaps support for the emergence of venture capital across the developing world should be a priority.

Entrepreneurship and Stages of Development

If specific firms are difficult to target due to informational problems, some have argued that a second best option is to target not firms but clusters or agglomerations of firms, noting that knowledge generation, learning, innovation, and economic activity tend to be localized processes (Braunerhjelm 2010: 6). Hence cluster approaches to entrepreneurship are important. The groundwork for such an approach needs to have started already by the factor-driven stage of development, as Table 14.2 implies.

Entrepreneurs are the essential drivers of innovation as Schumpeter recognized, and the ‘filters’ through which knowledge externalities spill over. It therefore makes sense for industrial-policy support for entrepreneurship to consider the formation and function of regional clusters (because of the localization of spillovers), and their linkages with the rest of the economy—and to ensure venture capital support at clusters. In such an environment an open economy that stimulates creativity and attracts the ‘best and the brightest’ receives priority in industrial policy.

14.5 Concluding remarks

A perennial challenge for industrial policy concerns not the ‘why’ but the ‘how’ (Rodrik 2007). In this chapter we have argued that an entrepreneurial approach to industrial policy offers an answer to the ‘how’ of industrial policy. This stands in contrast to past approaches, which have been characterized by heavy government interference and management of the economy, which have been characterized by the adoption of policies and strategies that were inappropriate for a country’s level of development, and which ignored the important role of innovation in economic growth and catching up.

There is as yet no substantial literature on the relationship between the stages of development, the evolving nature of entrepreneurship, and the orientation of the state—indeed this chapter is one of the first to make this link and to argue that this as yet emerging paradigm is essential in any future pathways to industrialization. However, we recognize that it is likely to be confounded by the difficulties that governments and international development organizations will encounter in identifying their stage of development, by the fact that stages overlap (as the third column in Table 14.2 suggests), that some countries may leapfrog stages, and that the instruments and measurements to guide industrial policy in each stage are not well understood. We have argued that the GEDI, which we described in Section 14.3, may be instructive in this regard.

Where a country ranks on the GEDI and what scores it has on the different institutional and individual level pillars can be indicators of the relative
Entrepreneurship and Stages of Development

strengths and weaknesses that face the country. These scores can be used to design industrial policy, shifting away from weaker pillars and concentrating on features that respond better, given the stage of development that country is in. The sequence of the sub-indices of the GEDI in the development process is important to note and offers suggestions for the aims of industrial policy.

We believe that industrial policy can play a role in fostering entrepreneurship for economic development. It can be used as a tool to overcome the market failures that concern entrepreneurs by ensuring that inefficient forms exit the market, by helping small firms grow, and by ensuring investment in human-capital development. The GEDI illustrates the quantitative and qualitative levels of entrepreneurial activity across the nations and countries at different stages of development. The different policy requirements needed to boost entrepreneurship and to generate growth at the three stages of development necessitate industrial policies that recognize the different kinds of entrepreneurial activity that may exist at different stages of development. The examples of countries like Korea, Singapore, and China are illustrative in this regard. The GEDI rankings can be an indicator of whether a country needs to focus on improving its entrepreneurial attitudes, activities, or aspirations.

The distinction made between various stages of development is of course one that should be made carefully, as a watertight demarcation or classification of countries is difficult. As the OECD (2011: 39) remarks ‘development has become more compressed, not only in terms of a higher pace but also because different development stages are pursued concurrently by emerging economies’. This means that care has to be taken to understand the way in which a particular economy is characterized in terms of these stages, where its industries and sectors are in terms of sources of growth, and how to ensure a policy differentiation. The demarcation of stage is thus still useful because it provides a basis for this demarcation of policy, which would otherwise have been difficult. It allows various stages of development and firm growth to be considered in the fine-tuning of industrial policy.
